1. Problem Statement

Current Situation and Problem:

Academic institutions increasingly rely on digital platforms for conducting examinations. However, standard assessment tools face two critical challenges. First, they are highly vulnerable to network instability; a simple Wi-Fi disconnection can cause a student to lose all their unsaved progress, leading to unfair grading and administrative overhead. Second, they often lack robust anti-cheating mechanisms and data security, making them susceptible to basic exploits (such as SQL injections) or unauthorized access to local test files.

Proposed Solution (Tamycs Shield):

To address these issues, we propose Tamycs Shield, a secure, 3-tier examination system. The system utilizes a modern technology stack to ensure both resilience and security. By implementing automated local caching encrypted with AES-256-GCM, the system guarantees that no student data is lost during network drops. Furthermore, the application will operate in a locked-down environment to prevent unauthorized access to external resources. This project aims to deliver a tamper-proof, highly reliable digital examination environment for universities.

---

2. Overall Description

Product Perspective Tamycs Shield is a self-contained, 3-tier web application designed to replace legacy monolithic assessment tools. It consists of:

Presentation Layer (Client): A dynamic interface built with React for students.

Application Logic Layer (Server): A Node.js backend handling API routing and security logic.

- Data Layer (Database): A PostgreSQL relational database.

User Classes

Administrators (Teachers): Users who create exams, manage question databases, and review student grades.

- Students: End-users who interact exclusively with the secure client interface to take exams.

---

3. Functional Requirements

Note: All requirements are assigned a unique ID for traceability and use the keyword "shall" to indicate an engineering obligation.

- FR-01: The system shall allow Administrators to create an account using a valid university email address and a password.
- FR-02: The Tamycs Server shall sanitize all text inputs from Administrators before storing them in the PostgreSQL database to prevent SQL injection attacks.
- FR-03: Upon the initiation of an exam, the Tamycs Client shall randomly shuffle the order of the questions to generate a unique test sequence for each student.
- FR-04: The Tamycs Client shall automatically save the student's current answers to an encrypted local backup file every 60 seconds.
- FR-05: If the network connection is lost, the Tamycs Client shall attempt to reconnect to the server every 30 seconds without interrupting the student's exam timer.
- FR-06: The system shall calculate and display the final grade to the Administrator within 5 seconds after a student submits their exam.

---

4. Non-Functional Requirements

Note: These requirements define how well the system performs, focusing on security, performance, and reliability.

- NFR-01 (Security): All user and administrator passwords shall be hashed using the bcrypt algorithm before being stored in the database.
- NFR-02 (Performance): The system shall respond to client API requests (such as submitting an answer) in less than 2 seconds.
- NFR-03 (Reliability): The Tamycs Client application shall maintain a crash-free session rate of 99.5% during a standard 2-hour examination period.
- NFR-04 (Security): Data transmission between the React frontend and Node.js backend shall be encrypted using standard HTTPS/TLS protocols.

---

5. External Interfaces

5.1 User Interfaces Overview The system features a Graphical User Interface (GUI). The student interface (Tamycs Client) shall operate in a full-screen, distraction-free mode displaying only the current question, multiple-choice answers, and a countdown timer.

5.2 Software Interfaces The React client shall communicate with the Node.js server exclusively via RESTful API endpoints using JSON formatting for all data payloads.

6 . System: Tamycs Client Application

This diagram illustrates the functional interactions between the student and the secure examination client interface.

A. Actors Identification

- **Primary Actor: Student** – The end-user who interacts with the React-based client interface to complete an assessment. The student is linked to the core functionality via an **Association** line.

B. Use Case Descriptions

The diagram breaks down the examination process into several specialized modules:

- **Take Exam**: The base use case initiated by the student to start the testing session.

- **Authenticate**: A mandatory security step requiring a valid university email and password before access is granted.
- **Display Questions**: The interface presents the test items, which are randomized to ensure a unique sequence for every student.
- **Select Answers**: The functional requirement allowing the student to choose multiple-choice options.
- **Submit Exam**: The final action where the student transmits their completed test to the Node.js server for grading.
- **Display Remaining Time**: A constant visual countdown timer to assist with student time management.

C. Logical Relations (UML)

The diagram relies exclusively on **Inclusion** relationships to define the system workflow:

- **`<<include>>`**: All dashed arrows point from the **Take Exam** case toward the other specific use cases.
- **Engineering Obligation**: This indicates that the "Take Exam" process cannot be completed without executing all the included sub-steps. In UML terms, these behaviors are required parts of the base use case and are not optional.

CLASS DIAGRAM

Class Structure

1. User (Abstract Class)

Serves as the base for all user types within the system.

- **Attributes:**
  - `# username: String`
  - `# password: String`
- **Method:**
  - `+ login(): boolean`

2. Student

Inherits from the User class and represents the end-user taking the exam.

- **Attributes:**
  - `- studentID: String`
- **Methods:**
  - `+ startExam()`
  - `+ submitExam()`

3. Exam

Represents the assessment entity.

- **Attributes:**
  - `- examID: String`
  - `- duration: int`
- **Method:**
  - `+ validateSubmission()`

4. Question

Details the individual items within an exam.

- **Attributes:**
  - `- questionID: String`
  - `- content: String`
- **Method:**
  - `+ checkAnswer()`

5. SecurityManager

Handles critical security constraints, such as AES-256 encryption for local caching.

- **Methods:**
  - `+ encryptData()`
  - `+ monitorActivity()`

Key Relationships

The diagram utilizes precise UML notations to define interactions:

- **Inheritance (Generalization)**: The **Student** is a specialization of the **User** (indicated by a hollow arrow pointing toward User).
- **Composition**: An **Exam** is composed of multiple **Questions**. If the exam is deleted, the associated questions are also destroyed (indicated by a solid diamond on the Exam side).
- **Association**: The **Student** takes an **Exam** (represented by a simple line connecting the two classes).
- **Dependency**: The **Student** relies on the **SecurityManager** for data protection (represented by a dashed line with an arrow).

Visibility Standards

- + **Public**: Accessible by any other class.
- – **Private**: Accessible only within the class (Encapsulation).
- # **Protected**: Accessible by the class and its subclasses (used for Inheritance between User and Student).

UML SEQUENCE / STATE /ACTIVITY DIAGRAMS

1. Sequence Diagram

Description

This sequence diagram illustrates the interaction between system components during an exam session.

Behavior

The student initiates the session by logging in.

The system validates credentials through the server.

An alternative flow (ALT) is used:

If authentication is successful → access is granted.

If authentication fails → an error is returned.

The student interacts with the system (answering questions).

The system processes the submission and calculates the result.

Purpose

To show the chronological order of interactions between system components and highlight conditional flows.

2. State Diagram

Description

This state diagram represents the lifecycle of a student during an exam.

States

Idle → initial state

Authenticated

Exam Started

Answering Questions

Submitted

Completed → final state

Transitions

login → Authenticated

startExam → Exam Started

answering → Answering Questions

submitExam → Submitted

calculateResult → Completed

Purpose

To describe how the system changes state in response to user actions.

3. Activity Diagram

Description

This activity diagram models the workflow of the exam process.

Flow

Student logs in

System validates credentials

Decision point:

If valid → continue

If invalid → terminate process

Start exam

Answer questions

Auto-save responses (periodic process)

Submit exam

Decision point:

If submission is valid → calculate result

Otherwise → reject submission

Display final result

Purpose

To illustrate the flow of activities and decision-making within the system.
